## 1 EXECUTIVE SUMMARY

PRESENT is a three-year EU Research and Innovation project between 8 companies and research institutions to create virtual digital humans (sentient agents) that look entirely naturalistic, demonstrate emotional sensitivity, establish an engaging dialogue, add sense to the experience, and act as trustworthy guardians and guides in the interfaces for AR, VR, and more traditional forms of media.

This document details the infrastructure design of the security module of PRESENT. We explain the tools used to implement it and provide descriptions about the different capabilities and functionalities of the module.

The main idea behind the security module is to use virtual identities to identify the parties interacting with the system. The design goal is to build a highly dynamic and decentralized system that allows the participants to be in control of their credentials.

There are two types of parties that can participate in the system: users and virtual agents. Both types will have verifiable credentials which will be used to validate their identity. For example, we will use name, surname and a front-facing image as part of the credential forming the identity of a user. Once the identity of a party is created, the security module will make use of different cryptographic tools and facial recognition to validate it.

The key technology that is used to implement the module is the Blockchain, which allow us to handle credentials in a decentralized manner. A description of this fundamental tool is out of the scope of this document and has been given in deliverable *D5.1 Blockchain Privacy Report*.

The security module can perform two functions. The first one is to register the credentials of the parties and the second one is to validate their identity from those credentials. All the other modules of the project will have access to these functionalities via a REST API.
