Background

- Increased use of digital trace data in social sciences

Our research

- Comparing digital trace and survey measures of FB use
- Using longitudinal survey, tracking apps, and FB donated data

DIGITAL TRACES

Recent increased interest in the social sciences

Considered an attractive alternative to surveys

- Superior quality
- Allow to overcome limitations

Have limitations that are often not addressed

- Can lead to biased results and incorrect findings

Compare digital trace and survey measures of FB use

- Allow errors in both sources
- Do not treat any source as 'gold standard'

Non-probability online panel in Germany

- N=2,100
- Survey with three waves around September 2021
- Tracking app installed on computer and/or mobile device
- FB donated data (for a sub-sample)

 Survey – 5-point Likert scale asking about frequency of use

 Tracking app – harmonizing to fit the survey question

- Three 10-day periods corresponding to survey waves
- Summing number of days in which FB was used on mobile & PC in each period
- Categorizing the usage variable in line with survey question

Hidden Markov models (HMMs)

-  Latent class models used to correct for measurement error in categorical, longitudinal data
-  Do not require any data source to be error-free
-  Use repeated measures of indicator(s) to extract information about the error from the data
-  Multiple-indicator HMMs correct for error in all sources simultaneously

The standard HMM

Markov assumption

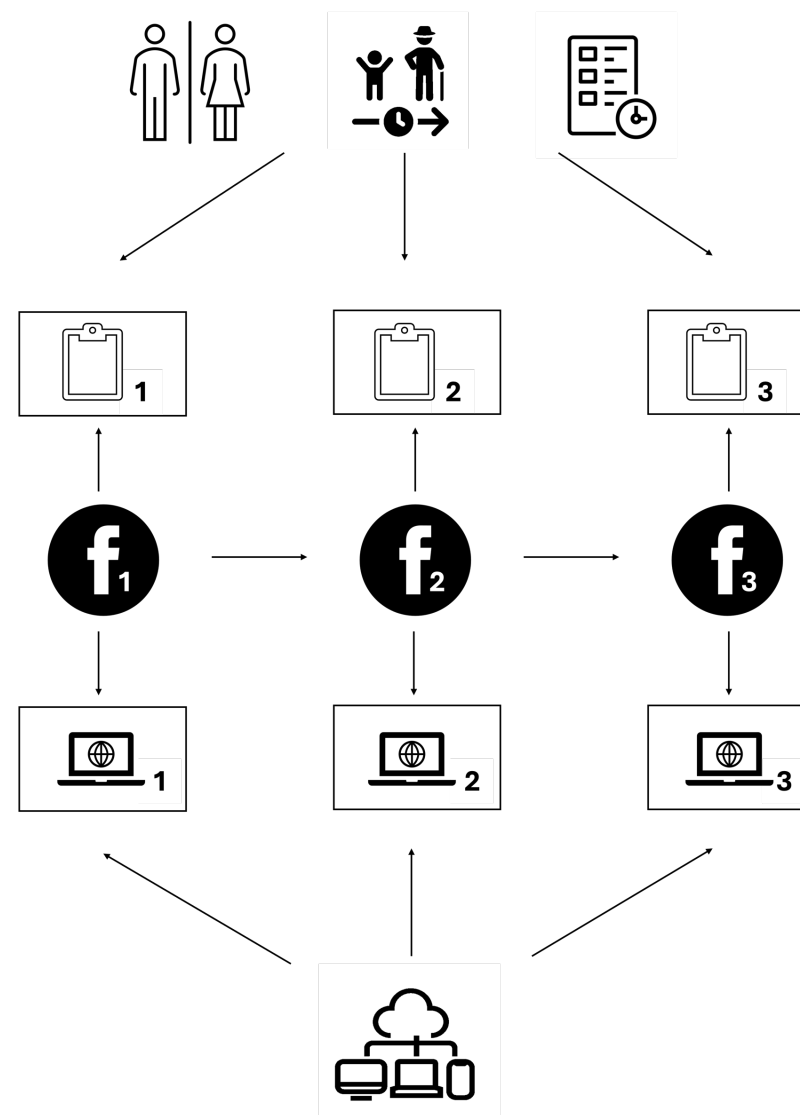

true state at time t only depends on true state at time $t-1$

Local independence assumption

observed state at time t only depends on true state at time t

Our model: two-indicator HMM

Model with 3 FB use classes fits data well

Both sources measure frequent (32.8%) and infrequent users relatively accurately (29.5%)

One class (37.7%) is characterized by large inconsistencies between the two sources

Facebook use frequency from **survey** and **tracking app**

Less likely to belong if both phone and PC are tracked ($\beta = -0.13, p < 0.05$)

More likely to belong if own more FB compatible devices ($\beta = 0.14, p < 0.05$)

Immigration background, education level, and political interest affect probability of belonging

Results confirmed by FB donated data

-  Available for $\pm 15\%$ of sample (\sim balanced distribution across classes)
-  Downloaded by respondents from own FB accounts
-  Used to estimate proportion of days in which FB was used around same time period

Facebook use frequency from **survey** and **tracking app**

Conclusions

Despite all their benefits, digital trace data are not perfect

- E.g., they can underestimate behaviors, such as FB use, if not all devices are tracked

We should take advantage of the good aspects, but also acknowledge the bad ones

When using digital trace, we should account for measurement error

👍 Funding for this study come from the *Baden-Württemberg Foundation* through the grant “Filter Bubbles, Alternative News and Political Polarization” (PI: R. Bach) and the *German Science Foundation (DFG)* through the grant “Evaluating Data Sources for Research into Political Reforms: (Non)probability Online Surveys and Big Data” (PIs: A. Blom, F. Keusch, & F. Kreuter).
